Q&A

Q1. The write-up mentions that any deviation in dimensions for fixed-shape and preplaced blocks is a hard-violation and should result in a score of 10, but then there is also a soft-constraint formula given to compute these violations, which are contradictory in nature. Could you please specify whether to consider this as a hard or soft constraint?

cost.py provided in the GitHub repo doesn't explicitly consider hard-constraint penalty ($M=10$) or the alpha, beta and gamma values given in the cost function. Does this mean that the organizers are yet to provide a proper validator program?

A1. Here is the contest repo, that addresses these concerns.
